<u>Dates</u> **Discussion** <u>Wiki</u> <u>Course</u> **Progress**

Association rule mining

In this notebook, you'll implement the basic pairwise association rule mining algorithm.

To keep the implementation simple, you will apply your implementation to a simplified dataset, namely, letters ("items") in words ("receipts" or "bar Having finished that code, you will then apply that code to some grocery store market basket data. If you write the code well, it will not be difficul building blocks from the letter case in the basket data case.

Problem definition

Let's say you have a fragment of text in some language. You wish to know whether there are association rules among the letters that appear in a problem:

- Words are "receipts"
- · Letters within a word are "items"

You want to know whether there are association rules of the form, $a \implies b$, where a and b are letters. You will write code to do that by calcula rule its *confidence*, $conf(a \implies b)$. "Confidence" will be another name for an estimate of the conditional probability of b given a, or $Pr[b \mid a]$.

Sample text input

Let's carry out this analysis on a "dummy" text fragment, which graphic designers refer to as the *lorem ipsum* (https://en.wikipedia.org/wiki/Loren

In [1]: | latin_text = """

Sed ut perspiciatis, unde omnis iste natus error sit voluptatem accusantium doloremque laudantium, totam rem aperiam eaque ipsa, quae ab illo inventore veritatis et quasi architecto beatae vitae dicta sunt, explicabo. print("First 100 characters:\n {} ...".format(latin_text[:100]))

First 100 characters:

Sed ut perspiciatis, unde omnis iste natus error sit voluptatem accusantium doloremque laudantium, ...

Exercise 0 (ungraded). Look up and read the translation of *lorem ipsum*!

Data cleaning. Like most data in the real world, this dataset is noisy. It has both uppercase and lowercase letters, words have repeated letters, all sorts of non-alphabetic characters. For our analysis, we should keep all the letters and spaces (so we can identify distinct words), but we sho case and ignore repetition within a word.

For example, the eighth word of this text is "error." As an *itemset*, it consists of the three unique letters, $\{e, o, r\}$. That is, treat the word as a set only keep the unique letters.

This itemset has three possible *itempairs*: $\{e, o\}$, $\{e, r\}$, and $\{o, r\}$.

Start by writing some code to help "clean up" the input.

Exercise 1 (normalize_string_test: 2 points). Complete the following function, normalize_string(s). The input s is a string (str object). should return a new string with (a) all characters converted to lowercase and (b) all non-alphabetic, non-whitespace characters removed.

Clarification. Scanning the sample text, latin_text, you may see things that look like special cases. For instance, inci[di]dunt and For these, simply remove the non-alphabetic characters and only separate the words if there is explicit whitespace.

For instance, inci[di]dunt would become incididunt (as a single word) and [do] would become do as a standalone word because original string has whitespace on either side. A period or comma without whitespace would, similarly, just be treated as a non-alphabetic character inside a word unless there is explicit whitespace. So e pluribus.unum basium would become e pluribusunum basium ev though your common-sense understanding might separate pluribus and unum.

Hint. Regard as a whitespace character anything "whitespace-like." That is, consider not just regular spaces, but also tabs, newlines, an perhaps others. To detect whitespaces easily, look for a "high-level" function that can help you do so rather than checking for literal space characters.

```
def normalize_string(s):
In [2]:
            assert type (s) is str
            ### BEGIN SOLUTION
            essential_chars = [c for c in s.lower() if c.isalpha() or c.isspace()]
            return ''.join(essential_chars)
             ### END SOLUTION
        # Demo:
        print(latin_text[:100], "...\n=>", normalize_string(latin_text[:100]), "...")
        Sed ut perspiciatis, unde omnis iste natus error sit
        voluptatem accusantium doloremque laudantium, ...
        sed ut perspiciatis unde omnis iste natus error sit
        voluptatem accusantium doloremque laudantium ...
In [3]: # `normalize_string_test`: Test cell
        norm_latin_text = normalize_string(latin_text)
        assert type(norm_latin_text) is str
        assert len(norm_latin_text) == 1694
        assert all([c.isalpha() or c.isspace() for c in norm_latin_text])
        assert norm_latin_text == norm_latin_text.lower()
        print("\n(Passed!)")
        (Passed!)
```

Exercise 2 (get_normalized_words_test: 1 point). Implement the following function, get_normalized_words(s). It takes as input a string s object). It should return a list of the words in s, after normalization per the definition of normalize string(). (That is, the input s may not be no

```
In [4]: | def get_normalized_words (s):
            assert type (s) is str
            ### BEGIN SOLUTION
            return normalize_string (s).split ()
            ### END SOLUTION
         # Demo:
         print ("First five words:\n{}".format (get_normalized_words (latin_text)[:5]))
         First five words:
         ['sed', 'ut', 'perspiciatis', 'unde', 'omnis']
In [5]: # `get_normalized_words_test`: Test cell
         norm_latin_words = get_normalized_words(norm_latin_text)
         assert len(norm_latin_words) == 250
         for i, w in [(20, 'illo'), (73, 'eius'), (144, 'deleniti'), (248, 'asperiores')]:
             assert norm latin words[i] == w
         print ("\n(Passed.)")
         (Passed.)
```

Exercise 3 (make_itemsets_test: 2 points). Implement a function, make_itemsets(words). The input, words, is a list of strings. Your function convert the characters of each string into an itemset and then return the list of all itemsets. These output itemsets should appear in the same orc corresponding words in the input.

```
In [6]: def make_itemsets(words):
            ### BEGIN SOLUTION
            return [set(w) for w in words]
            ### END SOLUTION
In [7]: # `make_itemsets_test`: Test cell
        norm_latin_itemsets = make_itemsets(norm_latin_words)
        # Lists should have the same size
        assert len(norm latin itemsets) == len(norm latin words)
        # Test a random sample
        from random import sample
        for i in sample(range(len(norm_latin_words)), 5):
             print('[{}]'.format(i), norm_latin_words[i], "-->", norm_latin_itemsets[i])
             assert set(norm_latin_words[i]) == norm_latin_itemsets[i]
        print("\n(Passed!)")
        [32] enim --> {'n', 'e', 'm', 'i'}
         [220] eveniet --> {'e', 'i', 'n', 'v', 't'}
        [23] et --> {'e', 't'}
        [224] repudiandae --> {'r', 'e', 'i', 'd', 'p', 'n', 'u', 'a'}
        [76] incididunt --> {'i', 'd', 'n', 'c', 'u', 't'}
        (Passed!)
```

Implementing the basic algorithm

Recall the pseudocode for the algorithm that Rachel and Rich derived together:

Find Assoc Rules (R, A, S)

Let T[a,b], C[a] < 0 Va,b \(\) A

for every
$$r \in R$$
 do

for every $\{a \in r, b \in r\}$ do

 $T[a,b] \leftarrow T[a,b] + 1$
 $T[b,a] \leftarrow T[b,a] + 1$

for every $a \in r$ do

 $C[a] \leftarrow C[a] + 1$

for every $(a \in A, b \in A)$ do

if $T[a,b]/C[a] \geq s$

then output $a \Rightarrow b$

In the following series of exercises, let's implement this method. We'll build it "bottom-up," first defining small pieces and working our way toward algorithm. This method allows us to test each piece before combining them.

Observe that the bulk of the work in this procedure is just updating these tables, T and C. So your biggest implementation decision is how to stop the second control of the work in this procedure is just updating these tables, T and C. So your biggest implementation decision is how to stop the second control of the work in this procedure is just updating these tables, T and T. good choice is to use a dictionary

Aside: Default dictionaries

Recall that the overall algorithm requires maintaining a table of item-pair (tuples) counts. It would be convenient to use a dictionary to store this t keys refer to item-pairs and the values are the counts.

However, with Python's built-in dictionaries, you always to have to check whether a key exists before updating it. For example, consider this cod

```
D = {'existing-key': 5} # Dictionary with one key-value pair
D['existing-key'] += 1 # == 6
D['new-kev'] += 1 # Error: 'new-kev' does not exist!
```

The second attempt causes an error because 'new-key' is not yet a member of the dictionary. So, a more correct approach would be to do the

```
D = {'existing-key': 5} # Dictionary with one key-value pair
if 'existing-key' not in D:
    D['existing-key'] = 0
D['existing-key'] += 1
if 'new-key' not in D:
    D['new-key'] = 0
D['new-key'] += 1
```

This pattern is so common that there is a special form of dictionary, called a *default dictionary*, which is available from the collections module: collections.defaultdict (https://docs.python.org/3/library/collections.html?highlight=defaultdict#collections.defaultdict).

When you create a default dictionary, you need to provide a "factory" function that the dictionary can use to create an initial value when the key of For instance, in the preceding example, when the key was not present the code creates a new key with the initial value of an integer zero (0). In default value is the one you get when you call int() with no arguments:

```
In [8]: | print (int ())
In [9]: from collections import defaultdict
        D2 = defaultdict (int) # Empty dictionary
        D2['existing-key'] = 5 # Create one key-value pair
        D2['existing-key'] += 1 # Update
        D2['new-key'] += 1
        print (D2)
        defaultdict(<class 'int'>, {'existing-key': 6, 'new-key': 1})
```

Exercise 4 (update_pair_counts_test: 2 points). Start by implementing a function that enumerates all item-pairs within an itemset and update table that tracks the counts of those item-pairs.

The signature of this function is:

```
def update_pair_counts(pair_counts, itemset):
```

where you pair_counts is the table to update and itemset is the itemset from which you need to enumerate item-pairs. You may assume pair default dictionary. Each key is a pair of items (a, b), and each value is the count. You may assume all items in itemset are distinct, i.e., that you as you would any set-like collection. Since the function will modify pair_counts, it does not need to return an object.

```
In [10]: | from collections import defaultdict
         from itertools import combinations # Hint!
         def update_pair_counts (pair_counts, itemset):
             Updates a dictionary of pair counts for
             all pairs of items in a given itemset.
             assert type (pair_counts) is defaultdict
             ### BEGIN SOLUTION
              for (a, b) in combinations (itemset, 2):
                  pair_counts[(a, b)] += 1
                  pair_counts[(b, a)]
              ### END SOLUTION
```

```
In [11]: | # `update_pair_counts_test`: Test cell
         itemset 1 = set("error")
         itemset_2 = set("dolor")
         pair_counts = defaultdict(int)
         update_pair_counts(pair_counts, itemset_1)
         assert len(pair_counts) == 6
         update_pair_counts(pair_counts, itemset_2)
         assert len(pair_counts) == 16
         print('"{}" + "{}"\n==> {}'.format (itemset_1, itemset_2, pair_counts))
         for a, b in pair_counts:
             assert (b, a) in pair_counts
             assert pair_counts[(a, b)] == pair_counts[(b, a)]
         print ("\n(Passed!)")
         "{'e', 'o', 'r'}" + "{'d', 'l', 'o', 'r'}"
```

```
==> defaultdict(<class 'int'>, {('e', 'o'): 1, ('o', 'e'): 1, ('e', 'r'): 1, ('r', 'e'): 1, ('o', 'r'):
'o'): 2, ('d', 'l'): 1, ('l', 'd'): 1, ('d', 'o'): 1, ('o', 'd'): 1, ('d', 'r'): 1, ('r', 'd'): 1, ('l'
('o', 'l'): 1, ('l', 'r'): 1, ('r', 'l'): 1})
(Passed!)
```

Exercise 5 (update_item_counts_test: 2 points). Implement a procedure that, given an itemset, updates a table to track counts of each item.

As with the previous exercise, you may assume all items in the given itemset (itemset) are distinct, i.e., that you may treat it as you would any collection. You may also assume the table (item_counts) is a default dictionary.

```
In [12]: def update_item_counts(item_counts, itemset):
             ### BEGIN SOLUTION
             for a in itemset:
                  item_counts[a] += 1
             ### END SOLUTION
In [13]:
         # `update_item_counts_test`: Test cell
         itemset_1 = set("error")
         itemset_2 = set("dolor")
         item_counts = defaultdict(int)
         update_item_counts(item_counts, itemset_1)
         assert len(item_counts) == 3
         update_item_counts(item_counts, itemset_2)
         assert len(item_counts) == 5
         assert item_counts['d'] == 1
         assert item_counts['e'] == 1
         assert item_counts['l'] == 1
         assert item_counts['o'] == 2
         assert item_counts['r'] == 2
         print("\n(Passed!)")
         (Passed!)
```

Exercise 6 (filter_rules_by_conf_test: 2 points). Given tables of item-pair counts and individual item counts, as well as a confidence thres rules that meet the threshold. The returned rules should be in the form of a dictionary whose key is the tuple, (a,b) corresponding to the rule a whose value is the confidence of the rule, $conf(a \Rightarrow b)$.

You may assume that if (a, b) is in the table of item-pair counts, then both a and b are in the table of individual item counts.

```
In [14]: def filter_rules_by_conf (pair_counts, item_counts, threshold):
             rules = {} # (item_a, item_b) -> conf (item_a => item_b)
             ### BEGIN SOLUTION
             for (a, b) in pair_counts:
                 assert a in item_counts
                  conf_ab = pair_counts[(a, b)] / item_counts[a]
                  if conf_ab >= threshold:
                      rules[(a, b)] = conf_ab
             ### END SOLUTION
             return rules
```

```
In [15]: # `filter_rules_by_conf_test`: Test cell
         pair_counts = {('man', 'woman'): 5,
                         ('bird', 'bee'): 3,
                         ('red fish', 'blue fish'): 7}
         item_counts = {'man': 7,
                         'bird': 9,
                         'red fish': 11}
          rules = filter_rules_by_conf (pair_counts, item_counts, 0.5)
         print("Found these rules:", rules)
         assert ('man', 'woman') in rules
         assert ('bird', 'bee') not in rules
         assert ('red fish', 'blue fish') in rules
         print("\n(Passed!)")
         Found these rules: {('man', 'woman'): 0.7142857142857143, ('red fish', 'blue fish'): 0.6363636363636364
```

Aside: pretty printing the rules. The output of rules above is a little messy; here's a little helper function that structures that output a little, whic for both debugging and reporting purposes.

```
In [16]: def gen_rule_str(a, b, val=None, val_fmt='{:.3f}', sep=" = "):
             text = "{} => {}".format(a, b)
             if val:
                 text = "conf(" + text + ")"
                 text += sep + val_fmt.format(val)
             return text
```

(Passed!)

```
def print_rules(rules):
   if type(rules) is dict or type(rules) is defaultdict:
        from operator import itemgetter
        ordered_rules = sorted(rules.items(), key=itemgetter(1), reverse=True)
    else: # Assume rules is iterable
        ordered_rules = [((a, b), None) for a, b in rules]
   for (a, b), conf_ab in ordered_rules:
        print(gen_rule_str(a, b, conf_ab))
# Demo:
print_rules(rules)
conf(man => woman) = 0.714
conf(red fish => blue fish) = 0.636
```

Exercise 7 (find_assoc_rules_test: 3 points). Using the building blocks you implemented above, complete a function find_assoc_rules sc implements the basic association rule mining algorithm and returns a dictionary of rules.

In particular, your implementation may assume the following:

(Passed!)

- 1. As indicated in its signature, below, the function takes two inputs: receipts and threshold.
- 2. The input, receipts, is a collection of itemsets: for every receipt r in receipts, r may be treated as a collection of unique items.
- 3. The input threshold is the minimum desired confidence value. That is, the function should only return rules whose confidence is at least tl

The returned dictionary, rules, should be keyed by tuples (a,b) corresponding to the rule $a\Rightarrow b$; each value should the the confidence conf(confidence). rule.

```
In [17]: | def find_assoc_rules(receipts, threshold):
              ### BEGIN SOLUTION
              pair_counts = defaultdict(int) # (item_a, item_b) -> count
              item_counts = defaultdict(int) # item -> count
              for itemset in receipts:
                  update_pair_counts(pair_counts, itemset)
                  update_item_counts(item_counts, itemset)
              rules = filter_rules_by_conf(pair_counts, item_counts, threshold)
              return rules
              ### END SOLUTION
In [18]: # `find_assoc_rules_test`: Test cell
          receipts = [set('abbc'), set('ac'), set('a')]
          rules = find_assoc_rules(receipts, 0.6)
          print("Original receipts as itemsets:", receipts)
          print("Resulting rules:")
          print_rules(rules)
          assert ('a', 'b') not in rules
          assert ('b', 'a') in rules
          assert ('a', 'c') in rules
          assert ('c', 'a') in rules
          assert ('b', 'c') in rules
          assert ('c', 'b') not in rules
          print("\n(Passed!)")
          Original receipts as itemsets: [{'c', 'b', 'a'}, {'c', 'a'}, {'a'}]
          Resulting rules:
          conf(b => c) = 1.000
          conf(c => a) = 1.000
          conf(b \Rightarrow a) = 1.000
          conf(a => c) = 0.667
```

Exercise 8 (latin_rules_test: 2 points). For the Latin string, latin_text, use your find_assoc_rules() function to compute the rules who is at least 0.75. Store your result in a variable named latin rules.

```
In [19]: # Generate `latin rules`:
         ### BEGIN SOLUTION
         latin_words = get_normalized_words(latin_text)
         latin_itemsets = make_itemsets(latin_words)
         latin_rules = find_assoc_rules(latin_itemsets, 0.75)
         ### END SOLUTION
         # Inspect your result:
         print_rules(latin_rules)
         conf(q => u) = 1.000
         conf(x => e) = 1.000
         conf(h => i) = 0.833
         conf(x => i) = 0.833
         conf(v => t) = 0.818
         conf(r => e) = 0.800
```

Next, let's analyze the rules common to Latin text *and* English text. That is, suppose we have two lists of commonly occurring rules, one for Latir (computed above as latin_rules) and one for English text; we'd like to know which pairs commonly occur in both.

For the English text, here is an English translation of the *lorem ipsum* text, encoded as the variable english_text in the next code cell:

```
In [21]: english_text = """
         But I must explain to you how all this mistaken idea
         of denouncing of a pleasure and praising pain was
         born and I will give you a complete account of the
         system, and expound the actual teachings of the great
         explorer of the truth, the master-builder of human
         happiness. No one rejects, dislikes, or avoids
         pleasure itself, because it is pleasure, but because
         those who do not know how to pursue pleasure
         rationally encounter consequences that are extremely
         painful. Nor again is there anyone who loves or
         pursues or desires to obtain pain of itself, because
         it is pain, but occasionally circumstances occur in
         which toil and pain can procure him some great
         pleasure. To take a trivial example, which of us
         ever undertakes laborious physical exercise, except
         to obtain some advantage from it? But who has any
         right to find fault with a man who chooses to enjoy
         a pleasure that has no annoying consequences, or
         one who avoids a pain that produces no resultant
         pleasure?
```

On the other hand, we denounce with righteous indignation and dislike men who are so beguiled and demoralized by the charms of pleasure of the moment, so blinded by desire, that they cannot foresee the pain and trouble that are bound to ensue; and equal blame belongs to those who fail in their duty through weakness of will, which is the same as saying through shrinking from toil and pain. These cases are perfectly simple and easy to distinguish. In a free hour, when our power of choice is untrammeled and when nothing prevents our being able to do what we like best, every pleasure is to be welcomed and every pain avoided. But in certain circumstances and owing to the claims of duty or the obligations of business it will frequently occur that pleasures have to be repudiated and annoyances accepted. The wise man therefore always holds in these matters to this principle of selection: he rejects pleasures to secure other greater pleasures, or else he endures pains to avoid worse pains.

In [22]: def intersect_keys(d1, d2):

Exercise 9 (intersect_keys_test: 2 points). Write a function that, given two dictionaries, finds the intersection of their keys.

```
assert type(d1) is dict or type(d1) is defaultdict
    assert type(d2) is dict or type(d2) is defaultdict
    ### BEGIN SOLUTION
    k1 = set(d1.keys())
    k2 = set(d2.keys())
    return k1.intersection(k2)
    ### END SOLUTION

In [23]: # `intersect_keys_test`: Test cell
from random import sample

    key_space = {'ape', 'baboon', 'bonobo', 'chimp', 'gorilla', 'monkey', 'orangutan'}
    val_space = range(100)

for trial in range(10): # Try 10 random tests
    d1 = {k: v for k, v in zip(sample(key_space, 4), sample(val_space, 4))}
    d2 = {k: v for k, v in zip(sample(key_space, 3), sample(val_space, 3))}
```

```
k_common = intersect_keys(d1, d2)
for k in key_space:
    is_common = (k in k_common) and (k in d1) and (k in d2)
    is_not_common = (k not in k_common) and ((k not in d1) or (k not in d2))
    assert is_common or is_not_common

print("\n(Passed!)")

(Passed!)
```

Exercise 10 (common_high_conf_rules_test: 1 points). Let's consider any rules with a confidence of at least 0.75 to be a "high-confidence ru

Write some code that finds all high-confidence rules appearing in *both* the Latin text *and* the English text. Store your result in a list named common_high_conf_rules whose elements are (a, b) pairs corresponding to the rules $a \Rightarrow b$.

```
In [24]: ### BEGIN SOLUTION
          english words = get normalized words(english text)
         english_itemsets = make_itemsets(english_words)
         english_rules = find_assoc_rules (english_itemsets, 0.75)
         common_high_conf_rules = intersect_keys(latin_rules, english_rules)
         ### END SOLUTION
         print("High-confidence rules common to _lorem ipsum_ in Latin and English:")
         print_rules(common_high_conf_rules)
         High-confidence rules common to _lorem ipsum_ in Latin and English:
         q => u
         x => e
In [25]: # `common_high_conf_rules_test`: Test cell
         assert len(common_high_conf_rules) == 2
         assert ('x', 'e') in common_high_conf_rules
         assert ('q', 'u') in common_high_conf_rules
         print("\n(Passed!)")
         (Passed!)
```

Putting it all together: Actual baskets!

Let's take a look at some real data that <u>someone (http://www.salemmarafi.com/code/market-basket-analysis-with-r/)</u> was kind enough to prepare exercise designed for the R programming environment.

First, here's a code snippet to load the data, which is a text file. If you are running in the Vocareum environment, we've already placed a copy of if you are running outside, this code will try to download a copy from the CSE 6040 website.

```
In [26]: def on_vocareum():
             import os
             return os.path.exists('.voc')
         def download(file, local_dir="", url_base=None, checksum=None):
             import os, requests, hashlib, io
             local_file = "{}{}".format(local_dir, file)
             if not os.path.exists(local_file):
                  if url_base is None:
                      url_base = "https://cse6040.gatech.edu/datasets/"
                 url = "{}{}".format(url_base, file)
                 print("Downloading: {} ...".format(url))
                 r = requests.get(url)
                 with open(local_file, 'wb') as f:
                      f.write(r.content)
             if checksum is not None:
                 with io.open(local_file, 'rb') as f:
                      body = f.read()
                      body_checksum = hashlib.md5(body).hexdigest()
                      assert body checksum == checksum, \
                          "Downloaded file '{}' has incorrect checksum: '{}' instead of '{}'".format(local_file,
                                                                                                      body_checksu
                                                                                                      checksum)
             print("'{}' is ready!".format(file))
         if on_vocareum():
             DATA_PATH = "../resource/asnlib/publicdata/"
             DATA_PATH = ""
         datasets = {'groceries.csv': '0a3d21c692be5c8ce55c93e59543dcbe'}
         for filename, checksum in datasets.items():
              download(filename, local_dir=DATA_PATH, checksum=checksum)
         with open('{}{}'.format(DATA_PATH, 'groceries.csv')) as fp:
             groceries_file = fp.read()
         print (groceries_file[0:250] + "...\n... (etc.) ...") # Prints the first 250 characters only
         print("\n(All data appears to be ready.)")
```

```
'groceries.csv' is ready!
citrus fruit, semi-finished bread, margarine, ready soups
tropical fruit, yogurt, coffee
whole milk
pip fruit, yogurt, cream cheese , meat spreads
other vegetables, whole milk, condensed milk, long life bakery product
whole milk, butter, yogurt, rice, abrasive clea...
... (etc.) ...
(All data appears to be ready.)
```

Each line of this file is some customer's shopping basket. The items that the customer bought are stored as a comma-separated list of values.

Exercise 11: Your task. (basket_rules_test: 4 points). Your final task in this notebook is to mine this dataset for pairwise association rules. Ir your code should produce (no pun intended!) a final dictionary, basket_rules, that meet these conditions (read carefully!):

- 1. The keys are pairs (a, b), where a and b are item names (as strings).
- 2. The values are the corresponding confidence scores, $conf(a \Rightarrow b)$.
- 3. Only include rules $a\Rightarrow b$ where item a occurs at least MIN_COUNT times and $\mathrm{conf}(a\Rightarrow b)$ is at least THRESHOLD.

Pay particular attention to Condition 3: not only do you have to filter by a confidence threshold, but you must exclude rules $a \Rightarrow b$ where the iter appear "often enough." There is a code cell below that defines values of MIN_COUNT and THRESHOLD, but your code should work even if we decide those values later on.

```
Aside: Why would an analyst want to enforce Condition 3?
```

Your solution can use the groceries_file string variable defined above as its starting point. And since it's in the same notebook, you may, of c any of the code you've written above as needed. Lastly, if you feel you need additional code cells, you can create them after the code cell marke solution but before the code marked, ### TEST CODE ###.

```
In [27]: # Confidence threshold
         THRESHOLD = 0.5
         # Only consider rules for items appearing at least `MIN_COUNT` times.
         MIN_COUNT = 10
In [28]: | ### BEGIN SOLUTION
         # Create itemsets and compute individual item counts
         baskets = []
         item_counts = defaultdict(int)
         for basket_raw in groceries_file.split('\n'):
             itemset = set(basket_raw.split(','))
              baskets.append(itemset)
              update_item_counts(item_counts, itemset)
          print("Found {} baskets.".format(len(baskets)))
         # Search for an initial set of association rules
         initial_basket_rules = find_assoc_rules(baskets, THRESHOLD)
         # Filter those rules to exclude infrequent items
         basket_rules = {}
         for (a, b), v in initial_basket_rules.items():
              if item_counts[a] >= MIN_COUNT:
                  basket_rules[(a, b)] = v
          ### END SOLUTION
         Found 9836 baskets.
```

```
### `basket_rules_test`: TEST CODE ###
print("Found {} rules whose confidence exceeds {}.".format(len(basket_rules), THRESHOLD))
print("Here they are:\n")
print_rules(basket_rules)
assert len(basket_rules) == 19
assert all([THRESHOLD <= v < 1.0 for v in basket_rules.values()])</pre>
ans_keys = [("pudding powder", "whole milk"), ("tidbits", "rolls/buns"), ("cocoa drinks", "whole milk")
"sausage"), ("rubbing alcohol", "whole milk"), ("honey", "whole milk"), ("frozen fruits", "other vegeta
eam", "other vegetables"), ("ready soups", "rolls/buns"), ("cooking chocolate", "whole milk"), ("cereal
ilk"), ("rice", "whole milk"), ("specialty cheese", "other vegetables"), ("baking powder", "whole milk"
alcohol", "butter"), ("rubbing alcohol", "citrus fruit"), ("jam", "whole milk"), ("frozen fruits", "whi
eam"), ("rice", "other vegetables")]
for k in ans_keys:
    assert k in basket_rules
print("\n(Passed!)")
Found 19 rules whose confidence exceeds 0.5.
Here they are:
conf(honey => whole milk) = 0.733
conf(frozen fruits => other vegetables) = 0.667
```

conf(cereals => whole milk) = 0.643

```
cont(rice => whole milk) = 0.613
conf(rubbing alcohol => whole milk) = 0.600
conf(cocoa drinks => whole milk) = 0.591
conf(pudding powder => whole milk) = 0.565
conf(jam => whole milk) = 0.547
conf(cream => other vegetables) = 0.538
conf(cream => sausage) = 0.538
conf(baking powder => whole milk) = 0.523
conf(tidbits => rolls/buns) = 0.522
conf(rice => other vegetables) = 0.520
conf(cooking chocolate => whole milk) = 0.520
conf(specialty cheese => other vegetables) = 0.500
conf(rubbing alcohol => citrus fruit) = 0.500
conf(rubbing alcohol => butter) = 0.500
conf(ready soups => rolls/buns) = 0.500
conf(frozen fruits => whipped/sour cream) = 0.500
(Passed!)
```

Fin! Don't forget to restart the kernel and re-run the notebook from scratch. If that seems to work, go ahead and submit the notebook in the auto
