Important note! Before you turn in this lab notebook, make sure everything runs as expected:

- First, restart the kernel -- in the menubar, select Kernel→Restart.
- Then run all cells -- in the menubar, select Cell→Run All.

Make sure you fill in any place that says YOUR CODE HERE or "YOUR ANSWER HERE."

#### Python review: Values, variables, types, lists, and strings

These first few notebooks are a set of exercises with two goals:

- 1. Review the basics of Python
- 2. Familiarize you with Jupyter

Regarding the first goal, these initial notebooks cover material we think you should already know from Chris Simpkins's (https://www.cc.gatech.edu/~simpkins/) Python Bootcamp (https://www.cc.gatech.edu/~simpkins/teaching/python-bootcamp/syllabus.htm based specifically on his offering to incoming students of the Georgia Tech MS Analytics in Fall 2016 (https://www.cc.gatech.edu/~simpkins/teaching/python-bootcamp/august2016.html).

Regarding the second goal, you'll observe that the bootcamp has each student install and work directly with the Python interpreter, whic locally on his or her machine (e.g., see Slide 5 of Chris's intro (https://www.cc.gatech.edu/~simpkins/teaching/python-bootcamp/slides/in python.html)). But in this course, we are using Jupyter Notebooks as the development environment. You can think of a Jupyter notebook web-based "skin" for running a Python interpreter---possibly hosted on a remote server, which is the case in this course. Here is a good on <u>Jupyter (https://www.datacamp.com/community/tutorials/tutorial-jupyter-notebook)</u>.

Note for OMSA (https://pe.gatech.edu/master-science-degrees/online-master-science-analytics) students. In this course we assume you are using Vocareum's deployment (https://www.vocareum.com/) of Jupyter. You also have an option to use other Jupyter environments, including installing and running Jupyter on your own system. We can't provide technical support to you if you choose to go those routes, but if you'd like to do that anyway, we recommend Microsoft Azure Notebooks (https://notebooks.azure.com/) as a web-hosted option, which we use in the on-campus class, or the Continuum Analytics Anaconda distribution (https://www.continuum.io/downloads) as a locally installed option.

Study hint: Read the test code! You'll notice that most of the exercises below have a place for you to code up your answer followed by "test cell." That's a code cell that checks the output of your code to see whether it appears to produce correct results. You can often lear by reading the test code. In fact, sometimes it gives you a hint about how to approach the problem. As such, we encourage you to try to the test cells even if they seem cryptic, which is deliberate!

Exercise 0 (1 point). Run the code cell below. It should display the output string, Hello, world!.

```
In [1]:
          Grade cell: hello world test
                                                                                                    Score: 1.0 / 1.
          print("Hello, world!")
```

Hello, world!

**Exercise 1** (x\_float\_test: 1 point). Create a variable named x\_float whose numerical value is one (1) and whose type is *floating-po*.

```
In [2]: | Student's answer
          x_float = 1.0
```

```
In [3]:
                                                                                             Score: 1.0 / 1.
         Grade cell: x_float_test
          # `x_float_test`: Test cell
          assert x_float == 1
          assert type(x_float) is float
          print("\n(Passed!)")
         (Passed!)
```

Exercise 2 (strcat\_ba\_test: 1 point). Complete the following function, strcat\_ba(a, b), so that given two strings, a and b, it returns concatenation of b followed by a (pay attention to the order in these instructions!).

```
In [4]:
         Student's answer
         def strcat_ba(a, b):
              assert type(a) is str
              assert type(b) is str
              return b + a
```

```
In [5]:
                                                                                         Score: 1.0 / 1.
         Grade cell: strcat_ba_test
         # `strcat_ba_test`: Test cell
         # Workaround: # Python 3.5.2 does not have `random.choices()` (available in 3.6+)
         def random_letter():
             from random import choice
             return choice('abcdefghijklmnopqrstuvwxyz')
         def random_string(n, fun=random_letter):
             return ''.join([str(fun()) for _ in range(n)])
         a = random_string(5)
         b = random_string(3)
         c = strcat_ba(a, b)
         print('strcat_ba("{}", "{}") == "{}"'.format(a, b, c))
         assert len(c) == len(a) + len(b)
         assert c[:len(b)] == b
         assert c[-len(a):] == a
         print("\n(Passed!)")
```

```
strcat_ba("qmlga", "yzj") == "yzjqmlga"
(Passed!)
```

**Exercise 3** (strcat\_list\_test: 2 points). Complete the following function, strcat\_list(L), which generalizes the previous function: a *list* of strings, L[:], returns the concatenation of the strings in reverse order. For example:

```
strcat_list(['abc', 'def', 'ghi']) == 'ghidefabc'
```

```
In [6]:
         Student's answer
         def strcat_list(L):
              assert type(L) is list
              return ''.join(L[::-1])
```

```
In [7]:
                                                                                          Score: 2.0 / 2.
         Grade cell: strcat_list_test
         # `strcat_list_test`: Test cell
         n = 3
         nL = 6
         L = [random_string(n) for _ in range(nL)]
         Lc = strcat_list(L)
         print('L == {}'.format(L))
          print('strcat_list(L) == \'{}\''.format(Lc))
         assert all([Lc[i*n:(i+1)*n] == L[nL-i-1] for i, x in zip(range(nL), L)])
         print("\n(Passed!)")
```

```
Solution: Notebook 1 | Module 0: Fundamentals (bootcamps) | FA21: Computing for Data Analysis | edX
```

```
L == ['vsp', 'yyn', 'yoh', 'iqv', 'kii', 'nby']
strcat_list(L) == 'nbykiiiqvyohyynvsp'
(Passed!)
```

**Exercise 4** (floor\_fraction\_test: 1 point). Suppose you are given two variables, a and b, whose values are the real numbers,  $a \ge 0$ negative) and b>0 (positive). Complete the function, floor\_fraction(a, b) so that it returns  $\lfloor \frac{a}{b} \rfloor$ , that is, the floor of  $\frac{a}{b}$ . The type of returned value must be int (an integer).

#### In [8]: Student's answer def is number(x): """Returns `True` if `x` is a number-like type, e.g., `int`, `float`, `Decimal()`, ... from numbers import Number return isinstance(x, Number) def floor\_fraction(a, b): assert is\_number(a) and a >= 0 assert is\_number(b) and b > 0 return int(a / b) # Alternative: Use the Python library call, `int(math.floor(a/b))`

```
In [9]:
                                                                                          Score: 1.0 / 1.
         Grade cell: floor_fraction_test
          # `floor_fraction_test`: Test cell
         from random import random
         a = random()
         b = random()
         c = floor_fraction(a, b)
         print('floor_fraction({}, {}) == floor({}) == {}'.format(a, b, a/b, c))
         assert b*c <= a <= b*(c+1)
         assert type(c) is int
         print('\n(Passed!)')
        floor_fraction(0.1322891757479948, 0.8374075207655717) == floor(0.15797466880528357) == 0
        (Passed!)
```

**Exercise 5** (ceiling\_fraction\_test: 1 point). Complete the function, ceiling\_fraction(a, b), which for any numeric inputs, a and corresponding to real numbers,  $a\geq 0$  and b>0, returns  $\left\lceil \frac{a}{b}\right\rceil$ , that is, the *ceiling* of  $\frac{a}{b}$ . The type of the returned value must be int.

```
In [10]:
          Student's answer
          def ceiling_fraction(a, b):
              assert is_number(a) and a >= 0
              assert is_number(b) and b > 0
              r = a/b - floor_fraction(a, b)
              return int(a/b + int(r > 0))
              # Alternative: Use Python's library call, `int(math.ceiling(a/b))`
```

```
In [11]:
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Score: 1.0 / 1.

### Python review: Basic collections of values

This notebook continues the review of Python basics based on <u>Chris Simpkins's (https://www.cc.gatech.edu/~simpkins/)</u> <u>Python Bootcar (https://www.cc.gatech.edu/~simpkins/teaching/python-bootcamp/syllabus.html)</u>. The focus here is on basic collections: tuples, dictionar and sets.

**Exercise 0** (minmax\_test: 1 point). Complete the function minmax(L), which takes a list L and returns a pair---that is, 2-element Pythor or "2-tuple"---whose first element is the minimum value in the list and whose second element is the maximum. For instance:

```
minmax([8, 7, 2, 5, 1]) == (1, 8)
```

```
In [1]: Student's answer

def minmax(L):
    assert hasattr(L, "__iter__")
    return (min(L), max(L))
```

```
In [2]:
                                                                                          Score: 1.0 / 1.
         Grade cell: minmax_test
         # `minmax_test`: Test cell
         L = [8, 7, 2, 5, 1]
         mmL = minmax(L)
         mmL_true = (1, 8)
         print("minmax({}) -> {} [True: {}]".format(L, mmL, mmL_true))
         assert type(mmL) is tuple and mmL == (1, 8)
         from random import sample
         L = sample(range(1000), 10)
         mmL = minmax(L)
         L_s = sorted(L)
         mmL\_true = (L\_s[0], L\_s[-1])
         print("minmax({}) -> {} [True: {}]".format(L, mmL, mmL_true))
         assert mmL == mmL_true
         print("\n(Passed!)")
        minmax([8, 7, 2, 5, 1]) -> (1, 8) [True: (1, 8)]
        minmax([900, 478, 446, 710, 463, 858, 124, 438, 633, 285]) -> (124, 900) [True: (124, 900)
```

**Exercise 1** (remove\_all\_test: 2 points). Complete the function remove\_all(L, x) so that, given a list L and a target value x, it return *copy* of the list that excludes *all* occurrences of x but preserves the order of the remaining elements. For instance:

```
remove_all([1, 2, 3, 2, 4, 8, 2], 2) == [1, 3, 4, 8]
```

(Passed!)

Note. Your implementation should not modify the list being passed into remove\_all.

```
In [3]: Student's answer

def remove_all(L, x):
    assert type(L) is list and x is not None
    return [v for v in L if v != x]
```

```
In [4]:
         Grade cell: remove_all_test
                                                                                          Score: 2.0 / 2.
         # `remove_all_test`: Test cell
         def test_it(L, x, L_ans):
             print("Testing `remove_all({}, {})`...".format(L, x))
             print("\tTrue solution: {}".format(L_ans))
             L_{copy} = L.copy()
             L_rem = remove_all(L_copy, x)
             print("\tYour computed solution: {}".format(L_rem))
             assert L_copy == L, "Your code appears to modify the input list."
             assert L_rem == L_ans, "The returned list is incorrect."
         # Test 1: Example
         test_it([1, 2, 3, 2, 4, 8, 2], 2, [1, 3, 4, 8])
         # Test 2: Random List
         from random import randint
         target = randint(0, 9)
```

```
L_input = []
L ans = []
for _ in range(20):
    v = randint(0, 9)
    L_input.append(v)
    if v != target:
        L_ans.append(v)
test_it(L_input, target, L_ans)
print("\n(Passed!)")
```

```
Testing `remove_all([1, 2, 3, 2, 4, 8, 2], 2)`...
        True solution: [1, 3, 4, 8]
       Your computed solution: [1, 3, 4, 8]
Testing `remove_all([6, 6, 1, 8, 0, 4, 9, 5, 6, 1, 9, 7, 8, 2, 2, 2, 1, 5, 1, 7], 9)`...
        True solution: [6, 6, 1, 8, 0, 4, 5, 6, 1, 7, 8, 2, 2, 2, 1, 5, 1, 7]
       Your computed solution: [6, 6, 1, 8, 0, 4, 5, 6, 1, 7, 8, 2, 2, 2, 1, 5, 1, 7]
(Passed!)
```

Exercise 2 (compress\_vector\_test: 2 points). Suppose you are given a vector, x, containing real values that are mostly zero. For instance,

```
x = [0.0, 0.87, 0.0, 0.0, 0.0, 0.32, 0.46, 0.0, 0.0, 0.10, 0.0, 0.0]
```

Complete the function, compress\_vector(x), so that returns a dictionary d with two keys, d['inds'] and d['vals'], which are lists the indicate the position and value of all the *non-zero* entries of x. For the previous example,

```
d['inds'] = [1, 5, 6, 9]
   d['vals'] = [0.87, 0.32, 0.46, 0.10]
```

**Note 1.** Your implementation must *not* modify the input vector x.

Note 2. If x contains only zero entries, d['inds'] and d['vals'] should be empty lists.

```
In [5]:
          Student's answer
```

```
def compress_vector(x):
    assert type(x) is list
    d = {'inds': [], 'vals': []}
    for i, v in enumerate(x):
        if v != 0.0:
            d['inds'].append(i)
            d['vals'].append(v)
    return d
```

```

     x (after call): [0.0, 0.0, 0.0, 0.0, 0.37, 0.61, 0.0, 0.0, 0.0, 0.43, 0.63, 0.64]
0, 0.32, 0.0, 0.0, 0.0, 0.0, 0.0]
     d: {'vals': [0.37, 0.61, 0.43, 0.32], 'inds': [5, 6, 11, 14]}
`x` has 10 zero entries.
     d: {'vals': [], 'inds': []}
(Passed!)
```

Repeated indices. Consider the compressed vector data structure, d, in the preceding exercise, which stores a list of indices (d['inds and a list of values (d['vals']).

Suppose we allow duplicate indices, possibly with different values. For example:

```
d['inds'] == [0, 3, 7, 3, 3, 5, 1]
   d['vals'] == [1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0]
```

In this case, the index 3 appears three times. (Also note that the indices d['ind'] need not appear in sorted order.)

Let's adopt the convention that when there are repeated indices, the "true" value there is the *sum* of the individual values. In other words true vector corresponding to this example of d would be:

```
# ind: 0
                    3*
                         4 5
   x == [1.0, 7.0, 0.0, 11.0, 0.0, 6.0, 0.0, 3.0]
```

Exercise 3 (decompress\_vector\_test: 2 points). Complete the function decompress\_vector(d) that takes a compressed vector d, w a dictionary with keys for the indices (inds) and values (vals), and returns the corresponding full vector. For any repeated index, the va should be summed.

The function should accept an optional parameter, n, that specifies the length of the full vector. You may assume this length is at least max(d['inds'])+1.

```
In [7]:
          Student's answer
```

```
def decompress_vector(d, n=None):
    # Checks the input
    assert type(d) is dict and 'inds' in d and 'vals' in d, "Not a dictionary or missing h
    assert type(d['inds']) is list and type(d['vals']) is list, "Not a list"
    assert len(d['inds']) == len(d['vals']), "Length mismatch"
    # Determine length of the full vector
    i_max = max(d['inds']) if d['inds'] else -1
    if n is None:
        n = i_max+1
    else:
        assert n > i_max, "Bad value for full vector length"
```

```
x = [0.0] * n
for i, v in zip(d['inds'], d['vals']):
    x[i] += v
return x
```

```

      n: 5
       => x[:5]: [0.0, 0.0, 0.0, 0.0, 0.0]
(Passed!)
```

Exercise 4 (find\_common\_inds\_test: 1 point). Suppose you are given two compressed vectors, d1 and d2, each represented as desc above and possibly with repeated indices. Complete the function find\_common\_inds(d1, d2) so that it returns a list of the indices they in common.

For instance, suppose:

```
d1 == {'inds': [9, 9, 1, 9, 8, 1], 'vals': [0.28, 0.84, 0.71, 0.03, 0.04, 0.75]}
   d2 == {'inds': [0, 9, 9, 1, 3, 3, 9], 'vals': [0.26, 0.06, 0.46, 0.58, 0.42, 0.21, 0.53, 0.76]}
```

Then:

```
find_{common_{inds}(d1, d2)} == [1, 9]
```

Note 1. The returned list must not have duplicate indices, even if the inputs do. In the example, the index 9 is repeated in both d1 and d2, but the output includes just one 9.

Note 2. In the returned list, the order of indices does not matter. For instance, the example shows [1, 9] but [9, 1] would also be valid.

```
In [9]:
         Student's answer
         def find_common_inds(d1, d2):
             assert type(d1) is dict and 'inds' in d1 and 'vals' in d1
             assert type(d2) is dict and 'inds' in d2 and 'vals' in d2
             s1 = set(d1['inds'])
             s2 = set(d2['inds'])
             return list(s1 & s2)
```

Important note! Before you turn in this lab notebook, make sure everything runs as expected:

- First, **restart the kernel** -- in the menubar, select Kernel→Restart.
- Then **run all cells** -- in the menubar, select Cell→Run All.

Make sure you fill in any place that says YOUR CODE HERE or "YOUR ANSWER HERE."

#### **Python review: More exercises**

This notebook continues the review of Python basics based on <u>Chris Simpkins's (https://www.cc.gatech.edu/~simpkins/)</u> <u>Python Bootcar (https://www.cc.gatech.edu/~simpkins/teaching/python-bootcamp/syllabus.html)</u>.

This particular notebook adapts the exercises that appeared with the <u>"Functional Programming" slides</u> (<a href="https://www.cc.gatech.edu/~simpkins/teaching/python-bootcamp/slides/functional-programming.html">https://www.cc.gatech.edu/~simpkins/teaching/python-bootcamp/slides/functional-programming.html</a>) of the Fall 2016 offering.

Consider the following dataset of exam grades, organized as a 2-D table and stored in Python as a "list of lists" under the variable name grades.

```
In [1]: grades = [
    # First line is descriptive header. Subsequent lines hold data
    ['Student', 'Exam 1', 'Exam 2', 'Exam 3'],
    ['Thorny', '100', '90', '80'],
    ['Mac', '88', '99', '111'],
    ['Farva', '45', '56', '67'],
    ['Rabbit', '59', '61', '67'],
    ['Ursula', '73', '79', '83'],
    ['Foster', '89', '97', '101']
]
```

**Exercise 0** (students\_test: 1 point). Write some code that computes a new list named students[:], which holds the names of the st as they from "top to bottom" in the table.

**Exercise 1** (assignments\_test: 1 point). Write some code to compute a new list named assignments[:], to hold the names of the clausesignments. (These appear in the descriptive header element of grades.)

**Exercise 2** (grade\_lists\_test: 1 point). Write some code to compute a new *dictionary*, named grade\_lists, that maps names of stu to *lists* of their exam grades. The grades should be converted from strings to integers. For instance, grade\_lists['Thorny'] == [106 80].

```
In [6]: Student's answer

# Create a dict mapping names to lists of grades.

# One-line solution: It works, and is vaguely clever, but it is not pretty.

#grade_lists = {L[0]: [int(g) for g in L[1:]] for L in grades[1:]}

# Alternative: More verbose but (arguably) more readable
grade_lists = {} # Empty dictionary
for L in grades[1:]:
    grade_lists[L[0]] = [int(g) for g in L[1:]]
```

```
In [7]:
                                                                                         Score: 1.0 / 1.

          print("\n(Passed!)")
         {'Foster': 95.6666666666667, 'Thorny': 90, 'Ursula': 78.333333333333, 'Farva': 56, 'Mac
         3333333333333, 'Rabbit': 62.333333333333336}
         (Passed!)
```

**Exercise 5** (grades\_by\_assignment\_test: 2 points). Write some code to compute a dictionary named grades\_by\_assignment, whos are assignment (exam) names and whose values are lists of scores over all students on that assignment. For instance, grades by assignment['Exam 1'] == [100, 88, 45, 59, 73, 89].

```
In [12]: Student's answer

# One-line solution: It works, and is vaguely clever, but it is not pretty.
#grades_by_assignment = {a: [int(L[k]) for L in grades[1:]] for k, a in zip(range(1, 4), c nments)}

# Alternative: More verbose but (arguably) more readable
```

(Passed!)

6. Farva: 56

In [18]:
